Association Rule Mining

- A very popular DM method in business
- Finds interesting relationships (affinities) between variables (items or events)
- Part of machine learning family
- Employs unsupervised learning
- There is no output variable
- Also known as **market basket analysis**
- Often used as an example to describe DM to ordinary people, such as the famous “relationship between diapers and beers!”

Association Rule Mining

- **Input:** the simple point-of-sale transaction data
- **Output:** Most frequent affinities among items
- Example: according to the transaction data...
“Customer who bought a laptop computer and a virus protection software, also bought extended service plan 70 percent of the time.”
- How do you use such a pattern/knowledge?
 - Put the items next to each other for ease of finding
 - Promote the items as a package (do not put one on sale if the other(s) are on sale)
 - Place items far apart from each other so that the customer has to walk the aisles to search for it, and by doing so potentially seeing and buying other items

Association Rule Mining

- A representative applications of association rule mining include
 - **In business:** cross-marketing, cross-selling, store design, catalog design, e-commerce site design, optimization of online advertising, product pricing, and sales/promotion configuration
 - **In medicine:** relationships between symptoms and illnesses; diagnosis and patient characteristics and treatments (to be used in medical DSS); and genes and their functions (to be used in genomics projects)...

Association Rule Mining

- Are all association rules interesting and useful?

A Generic Rule: $X \Rightarrow Y$ [S%, C%]

X, Y: products and/or services

X: Left-hand-side (LHS)

Y: Right-hand-side (RHS)

S: **Support:** how often **X** and **Y** go together

C: **Confidence:** how often **Y** go together with the **X**

Example: {Laptop Computer, Antivirus Software} \Rightarrow
{Extended Service Plan} [30%, 70%]

Association Rule Mining

- Algorithms are available for generating association rules
 - Apriori
 - Eclat
 - FP-Growth
 - + Derivatives and hybrids of the three
- The algorithms help identify the **frequent item sets**, which are, then converted to association rules

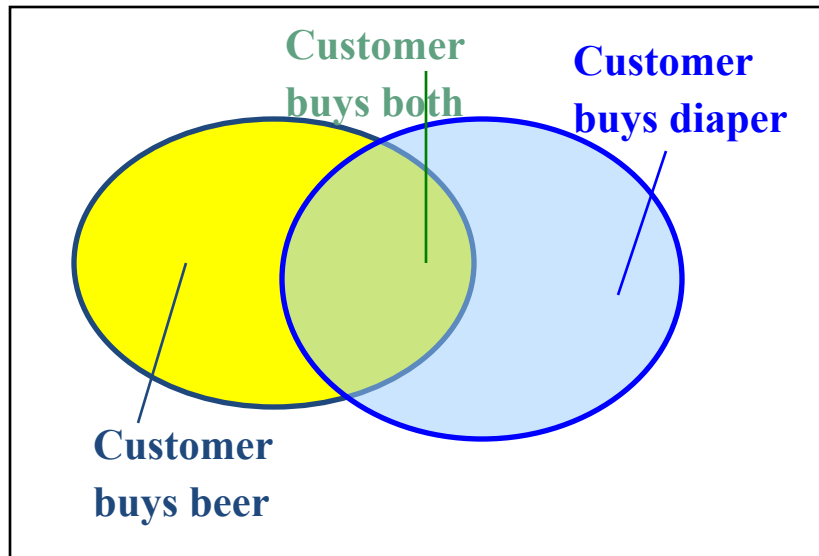

Association Rule Mining

- Apriori Algorithm
 - Finds subsets that are common to at least a minimum number of the itemsets
 - uses a bottom-up approach
 - frequent subsets are extended one item at a time (the size of frequent subsets increases from one-item subsets to two-item subsets, then three-item subsets, and so on), and
 - groups of candidates at each level are tested against the data for minimum

Basic Concepts: Frequent Patterns and Association Rules

Transaction-id	Items bought
10	A, B, D
20	A, C, D
30	A, D, E
40	B, E, F
50	B, C, D, E, F

- Itemset $X = \{x_1, \dots, x_k\}$
- Find all the rules $X \rightarrow Y$ with minimum support and confidence
 - **support**, s , probability that a transaction contains $X \cup Y$
 - **confidence**, c , conditional probability that a transaction having X also contains Y

Let $sup_{min} = 50\%$, $conf_{min} = 50\%$
 Freq. Pat.: $\{A:3, B:3, D:4, E:3, AD:3\}$

Association rules:

$A \rightarrow D$ (60%, 100%)

$D \rightarrow A$ (60%, 75%)

$A \rightarrow D$ (support = $3/5 = 60\%$, confidence = $3/3 = 100\%$)

$D \rightarrow A$ (support = $3/5 = 60\%$, confidence = $3/4 = 75\%$)

Market basket analysis

- Example
 - Which groups or sets of items are customers likely to purchase on a given trip to the store?
- Association Rule
 - *Computer* \rightarrow *antivirus_software*
[support = 2%; confidence = 60%]
 - A support of 2% means that 2% of all the transactions under analysis show that computer and antivirus software are purchased together.
 - A confidence of 60% means that 60% of the customers who purchased a computer also bought the software.

Association rules

- Association rules are considered interesting if they satisfy both
 - a **minimum support threshold** and
 - a **minimum confidence threshold**.

Frequent Itemsets, Closed Itemsets, and Association Rules

Let $I = \{I_1, I_2, \dots, I_m\}$ be a set of items. Let D , the task-relevant data, be a set of database transactions where each transaction T is a set of items such that $T \subseteq I$. Each transaction is associated with an identifier, called TID. Let A be a set of items. A transaction T is said to contain A if and only if $A \subseteq T$. An association rule is an implication of the form $A \Rightarrow B$, where $A \subset I$, $B \subset I$, and $A \cap B = \phi$. The rule $A \Rightarrow B$ holds in the transaction set D with support s , where s is the percentage of transactions in D that contain $A \cup B$ (i.e., the union of sets A and B , or say, both A and B). This is taken to be the probability, $P(A \cup B)$.¹ The rule $A \Rightarrow B$ has confidence c in the transaction set D , where c is the percentage of transactions in D containing A that also contain B . This is taken to be the conditional probability, $P(B|A)$. That is,

$$\text{Support } (A \rightarrow B) = P(A \cup B)$$

$$\text{Confidence } (A \rightarrow B) = P(B|A)$$

Support $(A \rightarrow B) = P(A \cup B)$
Confidence $(A \rightarrow B) = P(B|A)$

- The notation $P(A \cup B)$ indicates the probability that a transaction contains the union of set A and set B
 - (i.e., it contains every item in A and in B).
- This should not be confused with $P(A \text{ or } B)$, which indicates the probability that a transaction contains either A or B .

Does diaper purchase predict beer purchase?

- Contingency tables

Beer

Yes

No

No diapers	6	94	100
diapers	40	60	100

DEPENDENT (yes)

Beer

Yes

No

No diapers	23	77	100
diapers	23	77	100

INDEPENDENT (no predictability)

$$\text{Support } (A \rightarrow B) = P(A \cup B)$$

$$\text{Confidence } (A \rightarrow B) = P(B | A)$$

$$\text{Conf } (A \rightarrow B) = \text{Supp } (A \cup B) / \text{Supp } (A)$$

$$\text{Lift } (A \rightarrow B) = \text{Supp } (A \cup B) / (\text{Supp } (A) \times \text{Supp } (B))$$

Lift (Correlation)

$$\text{Lift } (A \rightarrow B) = \text{Confidence } (A \rightarrow B) / \text{Support}(B)$$

Lift

Lift = Confidence / Expected Confidence if Independent

Checking → Saving ↓	No (1500)	Yes (8500)	(10000)
No	500	3500	4000
Yes	1000	5000	6000

SVG=>CHKG Expect $8500/10000 = 85\%$ if independent

Observed Confidence is $5000/6000 = 83\%$

Lift = $83/85 < 1$.

Savings account holders actually LESS likely than others to have checking account !!!

Minimum Support and Minimum Confidence

- Rules that satisfy both a **minimum support threshold (min_sup)** and a **minimum confidence threshold (min_conf)** are called **strong**.
- By convention, we write support and confidence values so as to occur between 0% and 100%, rather than 0 to 1.0.

K-itemset

- itemset
 - A set of items is referred to as an **itemset**.
- K-itemset
 - An itemset that contains *k items* is a **k-itemset**.
- Example:
 - The set {*computer, antivirus software*} is a **2-itemset**.

Absolute Support and Relative Support

- **Absolute Support**

- The **occurrence frequency** of an itemset is the number of transactions that contain the itemset
 - frequency, support count, or count of the itemset
- Ex: 3

- **Relative support**

- Ex: 60%

Frequent Itemset

- If the **relative support** of an itemset I satisfies a **prespecified minimum support threshold**, then I is a **frequent itemset**.
 - i.e., the **absolute support** of I satisfies the corresponding **minimum support count threshold**
- The set of **frequent k -itemsets** is commonly denoted by L_K

Confidence

$$\text{confidence}(A \Rightarrow B) = P(B|A) = \frac{\text{support}(A \cup B)}{\text{support}(A)} = \frac{\text{support_count}(A \cup B)}{\text{support_count}(A)}$$

- the **confidence** of rule $A \rightarrow B$ can be easily derived from the support counts of A and $A \cup B$.
- once the support counts of A , B , and $A \cup B$ are found, it is straightforward to derive the corresponding association rules $A \rightarrow B$ and $B \rightarrow A$ and check whether they are strong.
- Thus the problem of mining association rules can be reduced to that of mining frequent itemsets.

Association rule mining: Two-step process

1. Find all frequent itemsets
 - By definition, each of these itemsets will occur at least as frequently as a predetermined minimum support count, *min_sup*.
2. Generate strong association rules from the frequent itemsets
 - By definition, these rules must satisfy minimum support and minimum confidence.

Efficient and Scalable Frequent Itemset Mining Methods

- The Apriori Algorithm
 - Finding Frequent Itemsets Using Candidate Generation

Apriori Algorithm

- **Apriori** is a seminal algorithm proposed by R. Agrawal and R. Srikant in 1994 for mining frequent itemsets for Boolean association rules.
- The name of the algorithm is based on the fact that the algorithm uses *prior knowledge of frequent itemset properties*, as we shall see following.

Apriori Algorithm

- Apriori employs an iterative approach known as a *level-wise search*, where *k*-itemsets are used to explore *(k+1)*-itemsets.
- First, the set of frequent 1-itemsets is found by scanning the database to accumulate the count for each item, and collecting those items that satisfy minimum support. The resulting set is denoted L_1 .
- Next, L_1 is used to find L_2 , the set of frequent 2-itemsets, which is used to find L_3 , and so on, until no more frequent *k*-itemsets can be found.
- The finding of each L_k requires one full scan of the database.

Apriori Algorithm

- To improve the efficiency of the level-wise generation of frequent itemsets, an important property called the **Apriori property**.
- Apriori property
 - *All nonempty subsets of a frequent itemset must also be frequent.*

Apriori algorithm
